ASSINGMENT NO.	9
TITLE	To write a program for implementing dictionary using Height balance tree.
PROBLEM STATEMENT /DEFINITION	A Dictionary stores keywords & its meanings. Provide facility for adding new keywords, deleting keywords, updating values of any entry. Provide facility to display whole data sorted in ascending/ Descending order. Also find how many maximum comparisons may require for finding any keyword. Use Height balance tree and find the complexity for finding a keyword.
OBJECTIVE	1. To understand concept of height balanced tree data structure. 2. To understand procedure to create height balanced tree.
OUTCOME	• Implement AVL using Object Oriented features. • Analyze working of various operations on AVL Tree.
S/W PACKAGES AND HARDWARE APPARATUS USED	• 64-bit Open source Linux or its derivative. • Open Source C++ Programming tool like G++/GCC.
REFERENCES	Data structures in C++ by Horowitz, Sahni.
INSTRUCTIONS FOR WRITING JOURNAL	1. Date 2. Assignment no. 3. Problem definition 4. Learning objective 5. Learning Outcome 6. Concepts related Theory 7. Algorithm/Pseudo code 8. Test cases 9. Conclusion/Analysis

Prerequisites:

- Binary tree and its implementation
- Concept of height balanced tree data structure

Learning Objectives:

- To understand concept of height balanced tree data structure.
- To understand procedure to create height balanced tree.
- To implement AVL Tree for Dictionary stores keywords & its meanings.

Learning Outcomes:
After successful completion of this assignment, students will be able to
- Implement AVL for dictionary using Object Oriented features.
- Analyze working of various operations on AVL Tree.

Concepts related Theory:

An empty tree is height balanced tree if T is a nonempty binary tree with TL and TR as its left and right sub trees. The T is height balance if and only if Its balance factor is 0, 1, -1.
AVL (Adelson- Velskii and Landis) Tree: A balance binary search tree. The best search time, that is O (log N) search times. An AVL tree is defined to be a well-balanced binary search tree in which each of its nodes has the AVL property. The AVL property is that the heights of the left and right sub-trees of a node are either equal or if they differ only by 1.

Representation:

What if the input to binary search tree comes in a sorted (ascending or descending) manner? It will then look like this −

If input 'appears' non-increasing manner   If input 'appears' in non-decreasing manner

It is observed that BST's worst-case performance is closest to linear search algorithms, that is O(n). In real-time data, we cannot predict data pattern and their frequencies. So, a need arises to balance out the existing BST.

Named after their inventor **Adelson**, **Velski** & **Landis**, **AVL trees** are height balancing binary search tree. AVL tree checks the height of the left and the right sub-trees and assures that the difference is not more than 1. This difference is called the **Balance Factor**.

Here we see that the first tree is balanced and the next two trees are not balanced −

Balanced   Not balanced   Not balanced

In the second tree, the left subtree of **C** has height 2 and the right subtree has height 0, so the difference is 2. In the third tree, the right subtree of **A** has height 2 and the left is missing, so it is 0, and the difference is 2 again. AVL tree permits difference (balance factor) to be only 1.

$$BalanceFactor = \text{height(left-sutree)} - \text{height(right-sutree)}$$

If the difference in the height of left and right sub-trees is more than 1, the tree is balanced using some rotation techniques.
Basic Operations:

AVL Rotations

To balance itself, an AVL tree may perform the following four kinds of rotations −

- Left rotation
- Right rotation
- Left-Right rotation
- Right-Left rotation

The first two rotations are single rotations and the next two rotations are double rotations. To have an unbalanced tree, we at least need a tree of height 2. With this simple tree, let's understand them one by one.
Left Rotation:
If a tree becomes unbalanced, when a node is inserted into the right subtree of the right subtree, then we perform a single left rotation −

Right unbalanced tree   Left Rotation   Balanced

In our example, node **A** has become unbalanced as a node is inserted in the right subtree of A's right subtree. We perform the left rotation by making **A** the left-subtree of B.

Right Rotation:

AVL tree may become unbalanced, if a node is inserted in the left subtree of the left subtree. The tree then needs a right rotation.

Left unbalanced Tree   Right Rotation   Balanced Tree

As depicted, the unbalanced node becomes the right child of its left child by performing a right rotation.
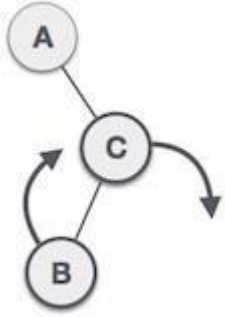

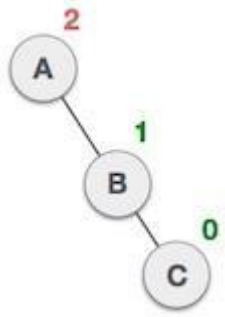

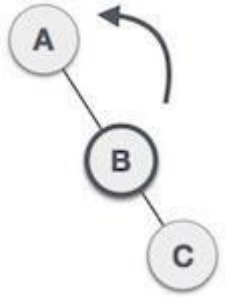

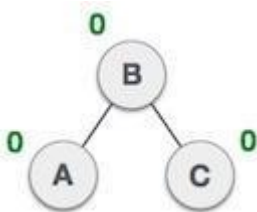

Left-Right Rotation

Double rotations are slightly complex version of already explained versions of rotations. To understand them better, we should take note of each action performed while rotation. Let's first check how to perform Left-Right rotation. A left-right rotation is a combination of left rotation followed by right rotation.

State	Action
	A node has been inserted into the right subtree of the left subtree. This makes **C** an unbalanced node. These scenarios cause AVL tree to perform left-right rotation.
	We first perform the left rotation on the left subtree of **C**. This makes **A**, the left subtree of **B**.
	Node **C** is still unbalanced, however now, it is because of the left-subtree of the left-subtree.
	We shall now right-rotate the tree, making **B** the new root node of this subtree. **C** now becomes the right subtree of its own left subtree.
	The tree is now balanced.

Right-Left Rotation

The second type of double rotation is Right-Left Rotation. It is a combination of right rotation followed by left rotation.

State	Action
	A node has been inserted into the left subtree of the right subtree. This makes **A**, an unbalanced node with balance factor 2.
	First, we perform the right rotation along **C** node, making **C** the right subtree of its own left subtree **B**. Now, **B** becomes the right subtree of **A**.
	Node **A** is still unbalanced because of the right subtree of its right subtree and requires a left rotation.
	A left rotation is performed by making **B** the new root node of the subtree. **A** becomes the left subtree of its right subtree **B**.
	The tree is now balanced.

Insert:-

1. If P is NULL, then
       I. P = new node
       II. P ->element = x
       III. P ->left = NULL
       IV. P ->right = NULL
       V. P ->height = 0
2. else if x>1 => x<P ->element
       a.) insert(x, P ->left)

       b.) if height of P->left -height of P ->right =2

             1. insert(x, P ->left)
             2. if height(P ->left) -height(P ->right) =2
                 if x<P ->left ->element
                     P =singlerotateleft(P)

                 else

                     P =doublerotateleft(P)

  3. else

       if x<P ->element

             a.) insert(x, P -> right)

             b.) if height (P -> right) -height (P ->left) =2
                 if(x<P ->right) ->element

                     P =singlerotateright(P)

                 else

                     P =doublerotateright(P)

4. else
Print already exits

5. m = AVL height (P->left)
6. n = AVL height (P->right)
7. d = max(m, n)
8. P->height = d+1
9. Stop

RotateWithLeftChild(AvlNode k2)

```
AvlNode k1 = k2.left;
k2.left = k1.right;
k1.right = k2;
k2.height = max( height( k2.left ), height( k2.right ) ) + 1;
k1.height = max( height( k1.left ), k2.height ) + 1;
return k1;
```

RotateWithRightChild(AvlNode k1)
```
AvlNode k2 = k1.right;
k1.right = k2.left;
k2.left = k1;
k1.height = max( height( k1.left ), height( k1.right ) ) + 1;
k2.height = max( height( k2.right ), k1.height ) + 1;
return k2;
```

doubleWithLeftChild(AvlNode k3)
```
k3.left = rotateWithRightChild( k3.left );
return rotateWithLeftChild( k3 );
```

doubleWithRightChild(AvlNode k1)
```
k1.right = rotateWithLeftChild( k1.right );
return rotateWithRightChild( k1 );
```

Review Questions:

1. What is AVL tree?
2. In an AVL tree, at what condition the balancing is to be done
3. When would one want to use a balance binary search tree (AVL) rather than an array data structure
